ReportRevisited

David Niederkofler, Erlend Lokna

2023-01-14

Introduction

Bayesian inference is a statistical method that allows us to estimate the probability of a hypothesis given some observed data. In the context of this report, Bayesian inference is used to better understand the distribution of posterior parameters in a data set. By using Bayesian inference, we can obtain more accurate estimates of the parameters that describe our data, and make more informed decisions about the underlying processes that generated the data. To calculate the parameter posteriors we will sample posterior predictive values with the help of Markov chain Monte Carlo Methods. Additionally, Monte Carlo methods are used to perform a Weibull survival analysis, which allows us to estimate the probability of the survival of a patient. Overall, this report aims to provide a better understanding of how the data was generated, and how the different factors in the data set may be related to the outcome of patient survival time.

Statistical Analysis of Covariates

In this section we will perform the Bayesian inference on the Covariates.

1. Age

The age of the patient in days.

1.1 Model selection

The data seems to follow a counting process so we assume it is poisson distribution $Poi(\lambda)$. Using the non informative Jeffreys prior, $h(\lambda) = \lambda^{-1}$, we can derive that the posterior for the parameter λ is Gamma distributed. $\lambda | x \sim Gamma(\alpha = \frac{1}{2} + \sum_{i=1}^{n} x_i, \beta = n)$

1.2 Results

The posterior distribution is estimated as:

Gamma(5700066 , 312)

With mean and variance:

mean: 18269.44 , variance: 58.55591

The 95% HDI interval calculates to:

```
## lower upper
## 18254.45 18284.40
## attr(,"credMass")
## [1] 0.95
```

This shows that the expected patient age is 50 years old.

2. Sex

The sex of the patients is encoded in a binary variable, where 0 means male and 1 means female.

2.1 Model selection

We assume a Bernoulli model $Ber(\theta)$ for the sex of the patient conditional on one parameter θ , the probability of the patient to be female. The density function is given by

$$f(x|\theta) = \theta^x (1-\theta)^{1-x},\tag{1}$$

where $x \in \{0, 1\}$. As a prior distribution for θ we use the natural conjugate family of the Bernoulli distribution, namely the Beta distribution, Beta(a, b), with two shape parameters a = b = 2 to give more weight to the middle of the interval [0, 1], knowing how females and males are represented in the general population. The density is given by

$$h(\theta) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \theta^{a-1} (1-\theta)^{b-1}, \tag{2}$$

for $\theta \in [0,1]$.

2.2 Results

From the given dataset we get the sample size n and the sum of the observations s:

```
n<-length(mydata$V6[!is.na(mydata$V6)])
s<-sum(mydata$V6)
n</pre>
```

[1] 312

S

[1] 276

Therefore the posterior distribution is Beta(2+s,2+n-s), which turns out to be Beta(278,38). From that we get

```
## Posterior mean: 0.8797468
```

Posterior mode: 0.8821656

Centered 95% Confidence Interval: [0.8417454 , 0.9132003]

And the HPD confidence Interval calculates to:

```
tst<-rbeta(1e5,278,38)
hdi(tst)
```

```
## lower upper
## 0.8435068 0.9149138
## attr(,"credMass")
## [1] 0.95
```

3 Ascictes

3.1 Model selection

Since the Ascictes - covariate has a 0-1 outcome we can assume that it is Bernoulli distributed with parameter θ . A natural conjugate prior for the Bernoulli distribution is the Beta distribution. The posterior beta distribution for the parameter is given by

$$Beta(\theta|a + \sum_{i=1}^{n} x_i, b + n - \sum_{i+1}^{n} x_i)$$

3.2 Results

The Beta distribution reduces to a simple uniform distribution. Since we have minimal prior knowledge about the parameters we will continue with a prior distribution that is uniformly distributed.

The posterior distribution has the following calculated information:

```
## Posterior mean: 0.08227848

## Posterior mode: 0.07961783

## Centered 95% Confidence Interval: [ 0.05235453 , 0.1119428 ]

With the HPD interval:

## lower upper
## 0.05127931 0.11035955
## attr(,"credMass")
## [1] 0.95
```

4. Hepatomegaly

The presence of hepatomegaly is encoded in a Binary variable, where 1 means hepatomegaly is present.

4.1 Model selection

We assume a Bernoulli model $Ber(\theta)$ for the presence of hepatomegaly in the patient, conditional on one parameter θ , the probability of the presence of hepatomegaly in the patient. The density function is given as stated earlier. As a prior distribution for θ we use the natural conjugate family of the Bernoulli distribution, namely the Beta distribution, Beta(a,b), with two shape parameters a=b=1, because we have no prior information. The density is given as above.

4.2 Results

From the given dataset we get the sample size n and the sum of the observations s:

```
n<-length(mydata$V8[!is.na(mydata$V8)]) s<-sum(mydata$V8) n

## [1] 312

s

## [1] 160

Therefore the posterior distribution is Beta(1+s,1+n-s), which turns out to be Beta(161,153). From that we get

## Posterior mean: 0.5126582

## Posterior mode: 0.5127389

## Centered 95% Confidence Interval: [ 0.4575015 , 0.5678225 ]
```

And the HPD confidence interval calculates to:

```
tst<-rbeta(1e5,161,153)
hdi(tst)

## lower upper
## 0.4578279 0.5677828
## attr(,"credMass")</pre>
```

5. Spiders

[1] 0.95

The presence of spiders is encoded in a Binary variable, where 1 means spiders are present.

5.1 Model selection

We assume a Bernoulli model $Ber(\theta)$ for the presence of spiders in patients conditional on one parameter θ , the probability of the presence of spiders in the patient. The density function is given as stated earlier. As a prior distribution for θ we use the natural conjugate family of the Bernoulli distribution, namely the Beta distribution, Beta(a,b), with two shape parameters a=b=1, because we have no prior information. The density is given as above.

5.2 Results

From the given dataset we get the sample size n and the sum of the observations s:

```
n<-length(mydata$V9[!is.na(mydata$V9)])
s<-sum(mydata$V9)
n
## [1] 312
s
## [1] 90</pre>
```

Therefore the posterior distribution is Beta(1 + s, 1 + n - s), which turns out to be Beta(91, 223). From that we get

```
## Posterior mean: 0.2911392
## Posterior mode: 0.2898089
## Centered 95% Confidence Interval: [ 0.2410228 , 0.341131 ]
```

And the HPD confidence interval calculates to:

```
tst<-rbeta(1e5,91,223)
hdi(tst)
```

```
## lower upper
## 0.2392825 0.3394949
## attr(,"credMass")
## [1] 0.95
```

6. Edema

The presence of edema is coded into (0, 0.5, 1). Where 0 is the class corresponding to no edema and no diuretic therapy for edema. The class 0.5 corresponds to edema present without diuretics, or edema resolved by diuretics. Lastly the class 1 corresponds to edema despite diuretic therapy.

```
## 0 0.5 1
## 263 29 20
```

We observe from the frequencies that most of the patients don't have edema and do not go to diuretic therapy for edema.

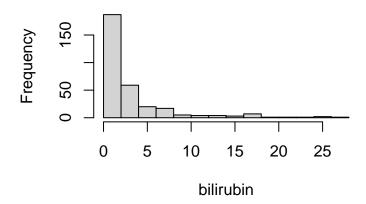

7. Bilirubin

The serum bilirubin of the patients is given in mg/dl.

7.1 Model Selection

We assume by inspecting the histogramm plot,

Histogram of bilirubin

that the data follows a exponential distribution with parameter λ . Density is given by

$$f(x|\lambda) = \lambda e^{-\lambda x} \tag{3}$$

As a prior for λ we use, the jeffreys non-informative prior, namely: $h(\lambda) \propto \frac{1}{\lambda}$.

7.2 Results

From the data we get the number of samples n and the sum of the samples s as

[1] 312

[1] 1015.9

That means the posterior distribution for λ is Gamma(n, s). Which turns out to be Gamma(312, 1015.9). From that we get

Posterior mean: 0.3071168

Posterior mode: 0.3061325

Centered 95% Confidence Interval: [0.2739805 , 0.3421174]

And the HPD confidence interval calculates to:

```
tst<-rgamma(1e5,312,1015.9)
hdi(tst)
```

```
## lower upper
## 0.2732791 0.3410037
## attr(,"credMass")
## [1] 0.95
```

8. Cholesterol

8.1 Model selection

We assume that the data is sampled from a poisson, $Poi(\lambda)$, distribution, and we use the non informative Jeffreys prior for the rate parameter.

8.2 Results

The posterior distribution is:

```
## Gamma( 104941.5 , 312 )
```

With mean and variance:

```
## mean: 336.351 , variance: 1.078048
```

The 95% HDI interval calculates to:

```
## lower upper
## 334.2960 338.3547
## attr(,"credMass")
## [1] 0.95
```

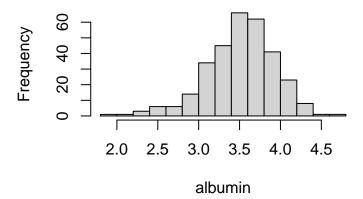

9. Albumin

The Albumin is given in mg/dl.

9.1 Model selection

By the histogram plot of the data we see,

Histogram of albumin

that albumin could be gamma distributed with shape and rate parameters a and b. We assume prior independence between a and b and use the marginal prior distributions Gamma(0.001, 0.001) for both of them.

9.2 Results

Using OpenBUGS and MCMC methods, we get posterior information about the parameters a and b:

```
n<-length(albumin[!is.na(albumin)])
X<-albumin
data1<-list("X","n")
params<-c("a" , "b")
inits<-list(a=1,b=1)
fit1<-bugs(data=data1,inits=list(inits),parameters.to.save=params,"model_albu.txt",n.chains=1, n.iter=2
fit1$summary</pre>
```

```

whereas the HPD confidence interval for b is

```
## lower upper
## 16.19 21.69
## attr(,"credMass")
## [1] 0.95
```

10. Urine

Urine copper in ug/day

10.1 Model selection

By observing the data we see that it seems to follow a poisson distribution.

10.2 Results

Using the non informative jeffreys prior we get the following posterior results:

The posterior distribution is:

```
## Gamma( 30271.5 , 312 )
```

With mean and variance:

```
## mean: 97.02404 , variance: 0.3109745
```

The 95% HDI interval calculates to:

```
## lower upper
## 95.91259 98.11055
## attr(,"credMass")
## [1] 0.95
```

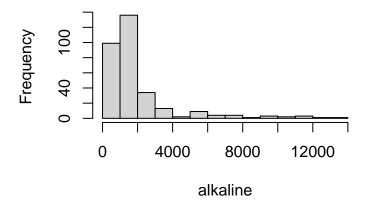

11. Alkaline

The data contains the units of alkaline phosphatase per liter of the patients.

11.1 Model selection

Since the units of alkaline per liter are integers, we assume that it is a counting process. Therefore we want to assume, that the data is poisson distributed conditional on one parameter λ . The histogram plot justifies our assumptions:

Histogram of alkaline

The density function of a single obervation is given as

$$f(x|\lambda) = e^{-\lambda} \frac{\lambda^x}{x!} \tag{4}$$

As a prior for λ we use the natural conjugate prior of the poisson distribution which is the gamma distribution. To not give a lot of prior information, we will use Gamma(0.001, 0.001).

11.2 Results

From our data we get the sample size n and the sum s over the sample:

[1] 312

[1] 618588.6

The posterior distribution for λ is given by Gamma(s + 0.001, n + 0.001) which in our case results to Gamma(618588.601, 312.001). This yields to:

Posterior mean: 1982.649

Posterior mode: 1982.646

Centered 95% Confidence Interval: [1977.712 , 1987.593]

And the HPD confidence interval calculates to:

```
tst<-rgamma(1e5,618588.601,312.001)
hdi(tst)
```

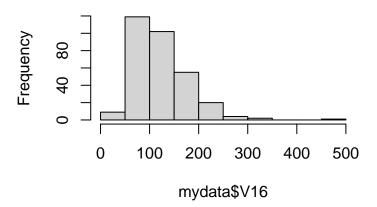

```
## lower upper
## 1977.718 1987.605
## attr(,"credMass")
## [1] 0.95
```

12 SGOT

Data provided in U/ml

12.1 Model selection

Histogram of SGOT

By inspecting the data and the histogram plot we can make the assumption that the data is sampled from a Gamma distribution with parameters a and b. Using MCMC methods included in the OpenBUGS library we can estimate the posterior parameters. We assume prior parameters a=b=0.001

12.2 Results

## attr(,"credMass")
## [1] 0.95
The 95% HDI for the b-parameter:
```

13

16. Histologic stage

The Histologic stage of the disease is a number in $\{1, 2, 3, 4\}$, where the stage increases with severeness. We will give here the frequencies of the stages in the dataset.

```
## 1 2 3 4
## 16 67 120 109
```

We see that, most patients have been diagnosed in the last to stages of the disease.

Weibull Survival Analysis

We will use a survival model, based on a hazard function, conditional on regression parameters and dependent on (now assumed) deterministic covariates. The hazard function is given by

$$\lambda(t|\alpha,\beta,\delta) = \delta \alpha t^{\alpha-1} e^{\beta^T z} \tag{5}$$

where z is the covariate vector. As prior distribution for the regression parameters β we will use normal distributions with 0 mean and $\sigma^2 = 1000$. For the parameters α and δ we use Gamma(0.001, 0.001) prior distribution. Prior independence is assumed. MCMC methods and OpenBUGS help us to get inference about our parameters:

```
##
                                      sd
                                                2.5%
                                                             25%
                                                                          50%

```

To assess the quality of our model, we compute standardized predictive residuals for uncensored data. For a uncencored survival time y(z), dependent of a covariate vector z, and the posterior predictive Y(z)|x, where x is the data used in the bayesian analysis, we define the standardized predictive residual as

$$d = \frac{y(z) - E(Y(z)|x)}{\sqrt{Var(Y(z)|x)}} \tag{6}$$

```
d<-abs((t[cens==1]-fit$mean$Y[cens==1])/fit$sd$Y[cens==1])
sum(d)</pre>
```

[1] 924.7143

The sum of the absolute values of the predictive residuals indicates the quality of the model. Now we will remove covariates with small regression coefficient means, trying to find better model fits. For the second model we kick out covariates for Age, Spiders and Cholesterol:

```
##
                     mean
                                     sd

We see that our model improved a little! For our last model we neglect, SGOT, and we get:

```

[1] 95.40789

Our model got worse! So we stop at the previous model and keep that as our survival model. Our remaining covariates are Edema, Bilirubin, Albumin, Urin copper, SGOT, prothrombin time and histologic stage. In the after-transplantation lifetime study, those covariates also play the most important role (except SGOT and urine copper)

Appendix

Bernoulli/Beta

A natural conjugate prior for the Bernoulli distribution is the Beta distribution.

$$f(x_i|\theta) = \theta^{x_i} (1-\theta)^{1-x_i}$$
$$L(\mathbf{x}|\theta) = \theta^{\sum_{i=1}^n x_i} (1-\theta)^{n-\sum_{i=1}^n x_i}$$
$$h(\theta) = Beta(a,b)$$

We proceed by calculating the posterior distribution for θ

$$h(\theta|\mathbf{x}) \propto L(\mathbf{x}|\theta)h(\theta) = \theta^{\sum_{i=1}^{n} x_i} (1-\theta)^{n-\sum_{i=1}^{n} x_i} \frac{1}{B(a,b)} \theta^{a-1} (1-\theta)^{b-1} I(0 < \theta < 1)$$

$$\propto Beta(\theta|a + \sum_{i=1}^{n} x_i, b + n - \sum_{i=1}^{n} x_i)$$

Poisson/Gamma

If our data X_1, \cdot, X_n are iid Poisson(λ) distributed then a gamma(α, β) prior on λ is a conjugate prior. The Likelyhood function is:

$$L(\lambda|\mathbf{x}) = \prod_{i=1}^{n} \frac{e^{-\lambda} \lambda^{\sum_{i=1}^{n} x_i}}{x_i!} = \frac{e^{-\lambda} \lambda^{\sum_{i=1}^{n} x_i}}{\prod_{i=1}^{n} x_i!}$$

Our gamma prior has the expression:

$$h(\lambda) = \frac{\beta^{\alpha}}{\Gamma(\alpha)} \lambda^{\alpha - 1} e^{-\beta \lambda}$$

Using bayes rule we find the following posterior:

$$h(\lambda|\mathbf{x}) \propto h(\lambda)L(\mathbf{x}|\lambda) \propto \lambda^{\sum_{i=1}^{n} x_i + \alpha - 1} e^{-(n+\beta)\lambda}$$

$$\propto gamma(\sum_{i=1}^{n} x_i + \alpha, n + \beta)$$

Poisson/Jeffreys prior

The density distribution for poisson is equal to

$$f(n|\lambda) = e^{-\lambda} \frac{\lambda^n}{n!}$$

The jeffreys prior $h(\theta)$ is a non informative prior distribution for a parameter space and its proportionality is expressed as

$$h(\theta) \propto \sqrt{\det I(\theta)}$$

$$I(\theta) = -E[\frac{\partial^2}{\partial \theta^2} log f(x|\theta)] = \frac{1}{\theta}$$

And the following jeffreys prior is thus

$$h(\theta) \propto \theta^{-\frac{1}{2}} I_{\theta > 0}$$

The posterior is calculated as follows

$$h(\theta|x) \propto f(\mathbf{x}|\theta)h(\theta) \propto e^{-n\theta}\theta^{-\frac{1}{2} + \sum_{i=1}^{n} x_i}$$

which is in fact a gamma distribution

$$\theta | x \sim Gamma(\alpha = \frac{1}{2} + \sum_{i=1}^{n} x_i, \beta = n)$$
